Digital Design & Computer Arch.

Lab 8.1 Supplement: Full System Integration

Prof. Onur Mutlu

ETH Zürich
Spring 2022
3 May 2022

Lab 8 Overview

- You will build a whole single-cycle processor and write assembly code that runs on the FPGA board.
- Don't worry! You have 2 sessions for the lab, and it will give you up to 14 points (+6 points from the reports).
- You will learn how a processor is built.
- Learn how the processor communicates with the outside world.
- Implement the MIPS processor and demonstrate a simple "snake" program on the FPGA starter kit.

Lab 8 Sessions

- Session I: The Crawling Snake
- Session II: Speed Up the Snake

Lab 8 Session I: The MIPS Processor

- Download the Vivado project from the course website
- A lot of parts are already implemented for you!
- What you will have to implement:
 - Compute the Instruction Memory address and read the instruction.
 - Connect the ALU.
 - Compute the Data Memory address and add the necessary wires.
 - Instantiate the Control Unit.

Lab 8 Session I: Memory-Mapped I/O

- Your goal is to control the 7-segment display with your assembly program.
- You will need to complete the I/O controller so the output of the processor will be correctly mapped to the display.

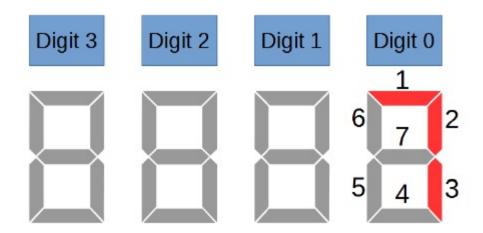

I/O in Assembly

- How do we communicate with the display?
- Memory Mapped I/O
 - We designate specific addresses for the I/O
 - We can read and write to those addresses.
 - Example

```
# write contents of $t0 into memory at address 0x7FF0
# so that the I/O controller can send it to the display
sw $t0, 0x7FF0($0)
```

Lab 8 Session I: The Crawling Snake

- You learned how to write assembly code in Lab 7
- We provide you with the code for a crawling snake on the 7-segment display

We will run this program on the processor you build in this lab!

Lab 8 Session II: Speed Up The Snake

- You will modify your assembly code to accept inputs.
 - The snake should crawl at different speeds for different inputs.
 - The inputs will be controlled by switches on the FPGA board.
- Modify the I/O controller to accept the inputs.
- Challenges
 - Change the direction of the snake.
 - Change the pattern of the snake.

Last Words

- You will build a whole single-cycle processor and write assembly code that runs on the FPGA board.
- You will learn how a processor is built.
- Learn how the processor communicates with the outside world.
- Implement the MIPS processor and demonstrate a simple "snake" program on the FPGA starter kit.
- You will have some questions to answer in the report.

Report Deadline

23:59, 27 May 2022
